

# 1. Two Sum

Given an array of integers `nums` and an integer `target`, return *indices of the two numbers such that they add up to `target`*.

You may assume that each input would have **exactly one solution**, and you may not use the *same* element twice.

You can return the answer in any order.

## Example 1:

**Input:** `nums = [2,7,11,15]`, `target = 9`

**Output:** `[0,1]`

**Explanation:** Because `nums[0] + nums[1] == 9`, we return `[0, 1]`.

## Example 2:

**Input:** `nums = [3,2,4]`, `target = 6`

**Output:** `[1,2]`

## Example 3:

**Input:** `nums = [3,3]`, `target = 6`

**Output:** `[0,1]`

## Constraints:

- $2 \leq \text{nums.length} \leq 10^4$
- $-10^9 \leq \text{nums}[i] \leq 10^9$
- $-10^9 \leq \text{target} \leq 10^9$
- **Only one valid answer exists.**

**Follow-up:** Can you come up with an algorithm that is less than  $O(n^2)$  time complexity?

---

```
class Solution {
    public int[] twoSum(int[] nums, int target) {
        HashMap<Integer,Integer> hm=new HashMap<>();
        int [] arr=new int[2];
        for(int i=0;i<nums.length;i++)
        {
            if(hm.containsKey(target-nums[i]))
            {
                arr[0]=hm.get(target-nums[i]);
                arr[1]=i;
            }
            else
            {
                hm.put(nums[i],i);
            }
        }
        return arr;
    }
}
```

---

## 20. Valid Parentheses

Given a string `s` containing just the characters `'('`, `)'`, `'{'`, `'}'`, `'['` and `']'`, determine if the input string is valid.

An input string is valid if:

1. Open brackets must be closed by the same type of brackets.
2. Open brackets must be closed in the correct order.
3. Every close bracket has a corresponding open bracket of the same type.

### Example 1:

**Input:** `s = "()"`  
**Output:** `true`

### Example 2:

**Input:** `s = "()[]{}"`  
**Output:** `true`

### Example 3:

**Input:** `s = "["`  
**Output:** `false`

### Constraints:

- $1 \leq s.length \leq 10^4$
- $s$  consists of parentheses only '()[]{}'.

```
class Solution {
    public boolean isValid(String s) {
        Stack<Character> stack = new Stack<Character>();
        for (char c : s.toCharArray()) {
            if (c == '(')
                stack.push(')');
            else if (c == '{')
                stack.push('}');
            else if (c == '[')
                stack.push(']');
            else if (stack.isEmpty() || stack.pop() != c)
                return false;
        }
        return stack.isEmpty();
    }
}
```

## 49. Group Anagrams

Given an array of strings `strs`, group **the anagrams** together. You can return the answer in **any order**.

An **Anagram** is a word or phrase formed by rearranging the letters of a different word or phrase, typically using all the original letters exactly once.

### Example 1:

**Input:** `strs = ["eat","tea","tan","ate","nat","bat"]`  
**Output:** `[["bat"],["nat","tan"],["ate","eat","tea"]]`

### Example 2:

**Input:** `strs = [""]`  
**Output:** `[[""]]`

### Example 3:

**Input:** strs = ["a"]

**Output:** [["a"]]

**Constraints:**

- $1 \leq \text{strs.length} \leq 10^4$
- $0 \leq \text{strs}[i].\text{length} \leq 100$
- $\text{strs}[i]$  consists of lowercase English letters.

1. 

```
public List<List<String>> groupAnagrams(String[] strs) {
    if (strs == null || strs.length == 0) return new ArrayList<>();
    Map<String, List<String>> map = new HashMap<>();
    for (String s : strs) {
        char[] ca = s.toCharArray();
        Arrays.sort(ca);
        String keyStr = String.valueOf(ca);
        if (!map.containsKey(keyStr)) map.put(keyStr, new ArrayList<>());
        map.get(keyStr).add(s);
    }
    return new ArrayList<>(map.values());
}
```
- 2.

```

import java.util.*;
class Solution {
    public List<List<String>> groupAnagrams(String[] strs) {
        HashMap<String,ArrayList<String>> hm=new HashMap<>();
        for(int i=0;i<strs.length;i++)
        {
            //each string in array
            //key is sorted string
            String sortedStringChar=sortString(strs[i]);
            if(!hm.containsKey(sortedStringChar))
            {
                ArrayList<String> alString=new ArrayList<>();
                alString.add(strs[i]);
                hm.put(sortedStringChar,alString);
            }
            else
            {
                ArrayList<String> al=hm.get(sortedStringChar);
                al.add(strs[i]);
                hm.put(sortedStringChar,al);
            }
        }
        System.out.println(hm);
        Collection<ArrayList<String>> valuesCollection =hm.values();
        ArrayList<List<String>> result=new ArrayList<List<String>>();
        valuesCollection.stream().forEach(i->{result.add(i);});
        return result;
    }
    public static String sortString(String inputString)
    {
        // Converting input string to character array
        char tempArray[] = inputString.toCharArray();

        // Sorting temp array using
        Arrays.sort(tempArray);

        // Returning new sorted string
        return new String(tempArray);
    }
}

```

## 125. Valid Palindrome

A phrase is a **palindrome** if, after converting all uppercase letters into lowercase letters and removing all non-alphanumeric characters, it reads the same forward and backward. Alphanumeric characters include letters and numbers.

Given a string *s*, return *true* if it is a **palindrome**, or *false* otherwise.

#### Example 1:

**Input:** `s = "A man, a plan, a canal: Panama"`

**Output:** `true`

**Explanation:** "amanaplanacanalpanama" is a palindrome.

#### Example 2:

**Input:** `s = "race a car"`

**Output:** `false`

**Explanation:** "raceacar" is not a palindrome.

#### Example 3:

**Input:** `s = " "`

**Output:** `true`

**Explanation:** s is an empty string "" after removing non-alphanumeric characters. Since an empty string reads the same forward and backward, it is a palindrome.

#### Constraints:

- $1 \leq s.length \leq 2 * 10^5$
- s consists only of printable ASCII characters.

---

#### 1. Array generic operation

```

class Solution {
    public boolean isPalindrome(String s) {
        s=s.toLowerCase().trim();
        s=s.replaceAll(" ", "");
        char[] ch=s.toCharArray();
        ArrayList<Character>arrayList=new ArrayList<>();
        for(char i:ch)
        {
            if((i>='a'&& i<='z')||(i>='0'&&i<='9'))
                arrayList.add(i);
        }
        for(int i=0;i<(arrayList.size()-1);i++)
        {
            if(arrayList.get(i)!=arrayList.get(arrayList.size() - 1 - i))
                return false;
        }
        return true;
    }
}

```

2. 2 pointer Note: Character.isLetterOrDigit(cHead) -> allows alphanumeric

```

public class Solution {
    public boolean isPalindrome(String s) {
        if (s.isEmpty()) {
            return true;
        }
        int head = 0, tail = s.length() - 1;
        char cHead, cTail;
        while(head <= tail) {
            cHead = s.charAt(head);
            cTail = s.charAt(tail);
            if (!Character.isLetterOrDigit(cHead)) {
                head++;
            } else if (!Character.isLetterOrDigit(cTail)) {
                tail--;
            } else {
                if (Character.toLowerCase(cHead) != Character.toLowerCase
(cTail)) {
                    return false;
                }
                head++;
                tail--;
            }
        }
        return true;
    }
}

```

## 128. Longest Consecutive Sequence

Given an unsorted array of integers `nums`, return *the length of the longest consecutive elements sequence*.

You must write an algorithm that runs in  $O(n)$  time.

### Example 1:

**Input:** `nums = [100,4,200,1,3,2]`

**Output:** 4

**Explanation:** The longest consecutive elements sequence is `[1, 2, 3, 4]`. Therefore its length is 4.

### Example 2:

**Input:** `nums = [0,3,7,2,5,8,4,6,0,1]`

**Output:** 9

### Constraints:

- $0 \leq \text{nums.length} \leq 10^5$
  - $-10^9 \leq \text{nums}[i] \leq 10^9$
-

```

class Solution {
    public int longestConsecutive(int[] nums) {
        // finding the number of digits that are continuous
        Arrays.sort(nums);
        //get the result as maximum continuous numbers
        int result=1;
        //continuous number count for each count
        int conti=1;
        for(int i=0;i<nums.length-1;i++)
        {
            //continuous number
            if(nums[i+1]==nums[i]+1)
            {
                conti++;
                result=conti>result?conti:result;
            }
            //same number
            else if(nums[i+1]==nums[i])
            {
                continue;
            }
            //reset for not continuous
            else
            {
                conti=1;
            }
        }
        //if length of nums is zero then no continuous number
        if(nums.length==0)
            return 0;
        else
            return result;
    }
}

```

## 150. Evaluate Reverse Polish Notation

You are given an array of strings `tokens` that represents an arithmetic expression in a Reverse Polish Notation ([http://en.wikipedia.org/wiki/Reverse\\_Polish\\_notation](http://en.wikipedia.org/wiki/Reverse_Polish_notation)).

Evaluate the expression. Return *an integer that represents the value of the expression*.

**Note** that:

- The valid operators are `'+'`, `'-'`, `'*'`, and `'/'`.
- Each operand may be an integer or another expression.
- The division between two integers always **truncates toward zero**.

- There will not be any division by zero.
- The input represents a valid arithmetic expression in a reverse polish notation.
- The answer and all the intermediate calculations can be represented in a **32-bit** integer.

#### Example 1:

**Input:** tokens = ["2","1","+","3","\*"]

**Output:** 9

**Explanation:**  $((2 + 1) * 3) = 9$

#### Example 2:

**Input:** tokens = ["4","13","5","/","+"]

**Output:** 6

**Explanation:**  $(4 + (13 / 5)) = 6$

#### Example 3:

**Input:** tokens = ["10","6","9","3","+","-11","\*","/","\*", "17","+","5","+"]

**Output:** 22

**Explanation:**  $((10 * (6 / ((9 + 3) * -11))) + 17) + 5$

$= ((10 * (6 / (12 * -11))) + 17) + 5$

$= ((10 * (6 / -132)) + 17) + 5$

$= ((10 * 0) + 17) + 5$

$= (0 + 17) + 5$

$= 17 + 5$

$= 22$

#### Constraints:

- $1 \leq \text{tokens.length} \leq 10^4$
  - $\text{tokens}[i]$  is either an operator: "+", "-", "\*", or "/", or an integer in the range  $[-200, 200]$ .
-

```

public class Solution {
    public int evalRPN(String[] tokens) {
        int a,b;
        Stack<Integer> S = new Stack<Integer>();
        for (String s : tokens) {
            if(s.equals("+")) {
                S.add(S.pop()+S.pop());
            }
            else if(s.equals("/")) {
                b = S.pop();
                a = S.pop();
                S.add(a / b);
            }
            else if(s.equals("*")) {
                S.add(S.pop() * S.pop());
            }
            else if(s.equals("-")) {
                b = S.pop();
                a = S.pop();
                S.add(a - b);
            }
            else {
                S.add(Integer.parseInt(s));
            }
        }
        return S.pop();
    }
}

```

## Note:

to convert string to integer

```
Integer.parseInt(s)
```

## 155. Min Stack

Design a stack that supports push, pop, top, and retrieving the minimum element in constant time.

Implement the `MinStack` class:

- `MinStack()` initializes the stack object.
- `void push(int val)` pushes the element `val` onto the stack.
- `void pop()` removes the element on the top of the stack.
- `int top()` gets the top element of the stack.
- `int getMin()` retrieves the minimum element in the stack.

You must implement a solution with  $O(1)$  time complexity for each function.

### Example 1:

#### Input

```
["MinStack", "push", "push", "push", "getMin", "pop", "top", "getMin"]  
[[], [-2], [0], [-3], [], [], [], []]
```

#### Output

```
[null, null, null, null, -3, null, 0, -2]
```

#### Explanation

```
MinStack minStack = new MinStack();  
minStack.push(-2);  
minStack.push(0);  
minStack.push(-3);  
minStack.getMin(); // return -3  
minStack.pop();  
minStack.top();    // return 0  
minStack.getMin(); // return -2
```

### Constraints:

- $-2^{31} \leq \text{val} \leq 2^{31} - 1$
  - Methods `pop`, `top` and `getMin` operations will always be called on **non-empty** stacks.
  - At most  $3 \cdot 10^4$  calls will be made to `push`, `pop`, `top`, and `getMin`.
-

```

class MinStack {
    Stack<Integer> st;
    PriorityQueue<Integer> pq;
    public MinStack() {
        st=new Stack<>();
        pq=new PriorityQueue<>();
    }

    public void push(int val) {
        st.push(val);
        pq.add(val);
    }

    public void pop() {
        pq.remove(st.pop());
    }

    public int top() {
        return st.peek();
    }

    public int getMin() {
        return pq.peek();
    }
}

/**
 * Your MinStack object will be instantiated and called as such:
 * MinStack obj = new MinStack();
 * obj.push(val);
 * obj.pop();
 * int param_3 = obj.top();
 * int param_4 = obj.getMin();
 */

```

## 217. Contains Duplicate

Given an integer array `nums` , return `true` if any value appears **at least twice** in the array, and return `false` if every element is distinct.

**Example 1:**

**Input:** `nums = [1,2,3,1]`  
**Output:** `true`

### Example 2:

**Input:** nums = [1,2,3,4]

**Output:** false

### Example 3:

**Input:** nums = [1,1,1,3,3,4,3,2,4,2]

**Output:** true

### Constraints:

- $1 \leq \text{nums.length} \leq 10^5$
- $-10^9 \leq \text{nums}[i] \leq 10^9$

```
class Solution {
    public boolean containsDuplicate(int[] nums) {
        HashSet<Integer> flag = new HashSet<Integer>();

        for(int i : nums) {
            if(!flag.add(i)) {
                return true;
            }
        }
        return false;
    }
}
```

## 238. Product of Array Except Self

Given an integer array `nums`, return an array `answer` such that `answer[i]` is equal to the product of all the elements of `nums` except `nums[i]`.

The product of any prefix or suffix of `nums` is **guaranteed** to fit in a **32-bit** integer.

You must write an algorithm that runs in  $O(n)$  time and without using the division operation.

### Example 1:

**Input:** nums = [1,2,3,4]

**Output:** [24,12,8,6]

### Example 2:

**Input:** nums = [-1,1,0,-3,3]

**Output:** [0,0,9,0,0]

### Constraints:

- $2 \leq \text{nums.length} \leq 10^5$
- $-30 \leq \text{nums}[i] \leq 30$
- The product of any prefix or suffix of nums is **guaranteed** to fit in a **32-bit** integer.

**Follow up:** Can you solve the problem in  $O(1)$  extra space complexity? (The output array **does not** count as extra space for space complexity analysis.)

```
class Solution {
    public int[] productExceptSelf(int[] nums) {
        int n = nums.length;
        int[] res = new int[n];
        // Calculate lefts and store in res.
        int left = 1;
        for (int i = 0; i < n; i++) {
            if (i > 0)
                left = left * nums[i - 1];
            res[i] = left;
        }
        // Calculate rights and the product from the end of the array.
        int right = 1;
        for (int i = n - 1; i >= 0; i--) {
            if (i < n - 1)
                right = right * nums[i + 1];
            res[i] *= right;
        }
        return res;
    }
}
```

## 242. Valid Anagram

Given two strings *s* and *t*, return *true* if *t* is an anagram of *s*, and *false* otherwise.

An **Anagram** is a word or phrase formed by rearranging the letters of a different word or phrase, typically using all the original letters exactly once.

**Example 1:**

**Input:** s = "anagram", t = "nagaram"

**Output:** true

**Example 2:**

**Input:** s = "rat", t = "car"

**Output:** false

**Constraints:**

- $1 \leq s.length, t.length \leq 5 * 10^4$
- s and t consist of lowercase English letters.

**Follow up:** What if the inputs contain Unicode characters? How would you adapt your solution to such a case?

```
class Solution {
    public boolean isAnagram(String s, String t) {
        int arr[] = new int[30];
        for (int i = 0; i < s.length(); i++)
        {
            int ch = (int)(s.charAt(i) - 'a');
            arr[ch]++;
        }
        for (int i = 0; i < t.length(); i++)
        {
            int ch = (int)(t.charAt(i) - 'a');
            arr[ch]--;
        }
        // int t=0;
        for (int i = 0; i < 30; i++)
        {
            if (arr[i] != 0)
                return false;
        }
        return true;
    }
}
```

## 347. Top K Frequent Elements

Given an integer array `nums` and an integer `k`, return *the k most frequent elements*. You may return the answer in **any order**.

### Example 1:

**Input:** `nums = [1,1,1,2,2,3]`, `k = 2`  
**Output:** `[1,2]`

### Example 2:

**Input:** `nums = [1]`, `k = 1`  
**Output:** `[1]`

### Constraints:

- $1 \leq \text{nums.length} \leq 10^5$
- $-10^4 \leq \text{nums}[i] \leq 10^4$
- `k` is in the range `[1, the number of unique elements in the array]`.
- It is **guaranteed** that the answer is **unique**.

**Follow up:** Your algorithm's time complexity must be better than  $O(n \log n)$ , where `n` is the array's size.

---

```

class Solution {
    public int[] topKFrequent(int[] nums, int k) {
        HashMap<Integer, Integer> map = new HashMap<>();
        for (int n : nums) {
            map.put(n, map.getOrDefault(n,0) + 1);
        }

        PriorityQueue<int[]> pq = new PriorityQueue<>((a,b) -> Integer.compare(a[1], b[1]));
        for (Map.Entry<Integer, Integer> e : map.entrySet()) {
            pq.add(new int[]{e.getKey(), e.getValue()});
            while (pq.size() > k) {
                pq.poll();
            }
        }

        int[] result = new int[k];
        for (int i = 0; i < k; i++) {
            result[i] = pq.poll()[0];
        }

        return result;
    }
}

```

## 739. Daily Temperatures

Given an array of integers `temperatures` represents the daily temperatures, return *an array* `answer` such that `answer[i]` is the number of days you have to wait after the  $i^{\text{th}}$  day to get a warmer temperature. If there is no future day for which this is possible, keep `answer[i] == 0` instead.

### Example 1:

**Input:** `temperatures = [73,74,75,71,69,72,76,73]`  
**Output:** `[1,1,4,2,1,1,0,0]`

### Example 2:

**Input:** `temperatures = [30,40,50,60]`  
**Output:** `[1,1,1,0]`

### Example 3:

**Input:** temperatures = [30,60,90]

**Output:** [1,1,0]

### Constraints:

- $1 \leq \text{temperatures.length} \leq 10^5$
- $30 \leq \text{temperatures}[i] \leq 100$

#### 1. Stacks

```
public int[] dailyTemperatures(int[] temperatures) {
    Stack<Integer> stack = new Stack<>();
    int[] ret = new int[temperatures.length];
    for(int i = 0; i < temperatures.length; i++) {
        while(!stack.isEmpty() && temperatures[i] > temperatures[stack.peek()]) {
            int idx = stack.pop();
            ret[idx] = i - idx;
        }
        stack.push(i);
    }
    return ret;
}
```

#### 2. Array

```
public int[] dailyTemperatures(int[] temperatures) {
    int[] stack = new int[temperatures.length];
    int top = -1;
    int[] ret = new int[temperatures.length];
    for(int i = 0; i < temperatures.length; i++) {
        while(top > -1 && temperatures[i] > temperatures[stack[top]]) {
            int idx = stack[top--];
            ret[idx] = i - idx;
        }
        stack[++top] = i;
    }
    return ret;
}
```
